## Summary

Fifty-five male runners had their sustainable endurance speeds established and represented using the 'classical' physiological model of endurance performance as the product of: maximal oxygen uptake; fractional utilisation; and running economy. Correlation coefficients were calculated between spatiotemporal gait parameters and model components. Parameters indicative of higher mass-specific vertical ground forces – higher flight time and lower duty factor - had the strongest relationships with sustainable speed. These components were also related to the product of maximal oxygen uptake and fractional utilisation, but not to running economy. It is unclear whether technique directly influenced oxygen uptake, but athletes who applied larger mass-specific vertical ground forces sustained higher running speeds.

## Introduction

In the 'classical' physiological model of endurance performance, maximum sustainable running speed ( $S_s$ ) can be expressed using three parameters [1]:

$$S_s = \dot{V}O_{2max} \times \%V\dot{O}_{2max} \times RE, \quad (1)$$

where  $\dot{V}O_{2max}$  is maximal oxygen uptake (in  $\text{ml.kg}^{-1}.\text{min}^{-1}$ ),  $\%V\dot{O}_{2max}$  is the percentage of  $\dot{V}O_{2max}$  at  $S_s$ , and  $RE$  is running economy [in  $\text{km.h}^{-1} \cdot \dot{V}O_2^{-1}$  ( $\text{ml.kg}^{-1}.\text{min}^{-1}$ )].

Typically, it is thought that running technique influences performance via  $RE$ , however different elements of technique have been shown to relate to performance than to  $RE$  [2]. The study aim was to relate technique to the components of Equation 1 and to competition running performance.

## Methods

Fifty-five healthy male endurance runners (age:  $27.1 \pm 7.4$  yrs; height:  $1.79 \pm 0.06$  m; mass:  $67.2 \pm 6.4$  kg) performed an incremental treadmill running test during which speed at lactate turnpoint ( $S_{LT}$ ) was determined from analysis of blood lactate, and  $RE$ ,  $\dot{V}O_{2peak}$ , and  $\%V\dot{O}_{2peak}$  were established from pulmonary gas exchange data. Peak  $\dot{V}O_2$  values were used as estimates of maximum values and  $S_{LT}$  as an estimate of  $S_s$ . Spatiotemporal variables stride length ( $SL$ ), stride rate ( $SR$ ), stance time ( $ST$ ), flight time ( $FT$ ), and duty factor ( $DF$ ) were calculated using 3D kinematics. The highest speed at which all subjects were at or below  $S_{LT}$  ( $16 \text{ km.h}^{-1}$ ) was analysed to avoid the confounding effect of comparing technique parameters at different speeds. Runners' season's best times for distances from 1500 m to marathon were collected and converted using IAAF points to an equivalent speed over 10 km ( $S_{BT}$ ). Theoretical speed at peak oxygen

uptake ( $S_{V\dot{O}2max} = \dot{V}O_{2max} \times RE$ ), and rate of oxygen uptake at  $S_s$  ( $V\dot{O}_2 = \dot{V}O_{2max} \times \%V\dot{O}_{2max}$ ) were also derived from Equation 1. Spatiotemporal parameters were then correlated to  $\dot{V}O_{2max}$ ,  $\%V\dot{O}_{2max}$ ,  $RE$ ,  $S_{V\dot{O}2max}$ ,  $V\dot{O}_2$ ,  $S_s$ , and  $S_{BT}$  using Pearson correlation coefficients.

## Results and Discussion

Parameters indicative of higher mass-specific vertical ground reaction forces (higher  $FT$  and lower  $DF$ ) had the strongest relationships with better  $S_s$  and  $S_{BT}$ , displaying consistently stronger relationships with  $S_{BT}$  than  $S_s$  (Table 1). No spatiotemporal parameters were individually related to  $\dot{V}O_{2max}$ ,  $\%V\dot{O}_{2max}$ , or  $RE$ . However, the product of  $\dot{V}O_{2max}$  and  $\%V\dot{O}_{2max}$  -  $V\dot{O}_2$  - was also correlated to  $FT$  and  $DF$ . Therefore, relationships between spatiotemporal parameters and  $S_s$  seem to have been driven by relationships with  $\dot{V}O_{2max}$  and  $\%V\dot{O}_{2max}$ , and were independent of  $RE$ .

**Table 1:** Pearson correlation coefficients (r) between spatiotemporal parameters, and performance and physiological parameters.

	<i>SL</i>	<i>SR</i>	<i>ST</i>	<i>FT</i>	<i>DF</i>
$\dot{V}O_{2max}$	0.10	-0.10	-0.15	0.18	-0.18
$\%V\dot{O}_{2max}$	0.09	-0.09	-0.21	0.22	-0.24
<i>RE</i>	-0.03	0.03	0.11	-0.09	0.10
$S_{V\dot{O}2max}$	0.07	-0.07	-0.04	0.08	-0.07
$V\dot{O}_2$	0.17	-0.17	-0.31*	0.35**	-0.36**
$S_s$	0.19	-0.19	-0.26	0.33*	-0.33*
$S_{BT}$	0.36**	-0.36**	-0.29*	0.48***	-0.45***

\*  $p < 0.05$ , \*\*  $p < 0.01$ , \*\*\*  $p < 0.001$

## Conclusions

Of the components in the classical model of endurance performance, the product of  $\dot{V}O_{2max}$  and  $\%V\dot{O}_{2max}$  was related to spatiotemporal gait parameters, but  $RE$  was not. It is unclear whether duty factor directly influenced oxygen uptake and performance, as has been observed in isolated limb exercises [3], or if other factors mediated this relationship. Regardless, athletes who applied larger mass-specific vertical ground forces sustained higher running speeds.
